# Familial Hypertrophic Cardiomyopathy (FHC)

FHC: - Prevalence 1:500, most frequent disease of the myocardium

- frequent cause of sudden death, particularly in young adults including athletes
- inherited as a mendelian autosomal dominant trait, caused by mutations in any 1 of 10 genes

from Maron, BJ, JAMA 2002

**Hypertrophy of LV and Septum**

Adapted from G. Farrer-Brown, Farbatlas der Herzkrankheiten, 1980

## Typical symptoms:

- ◆ asymmetric left ventricular hypertrophy
- ◆ cardiac arrhythmias
- ◆ fainting
- ◆ ventricular fibrillation

→ frequent cause of sudden death, particularly in young athletes

# FHC is mainly caused by mutations in genes encoding proteins of the cardiac sarcomere

# Myosin head domain with some mutations studied in biopsies from FHC patients

# Known proteins with mutations and the frequency of the mutations

HCM Disease Genes and Mutation Frequency\*

Codon 723: Wildtyp: CGC  
R723G: GGC

# Summary and Conclusions

- Genome Editors offer sophisticated new opportunities to manipulate the mammalian genome with a previously unknown precision and efficiency.
- HDR can be used to integrate point mutations, short insertions, or longer sequences at a desired locus within the genome.
- HDR efficiency can be increased by the use of an asymmetric donor DNA (>50%).
- The mutation should be within the range of 0-5 bp to the cut to ensure integration of the mutation.
- NHEJ can be prevented by the use of specific inhibitors of DNA Ligase IV.
- Additional NHEJ events can be repaired by a second round of genome editing or can be prevented by modified genome editors that lead to a direct base editing without cutting the DNA.
